

TARDIS (Time and Remanence Decay In SRAM): Secure Time Keeping For Embedded Devices Without Clocks

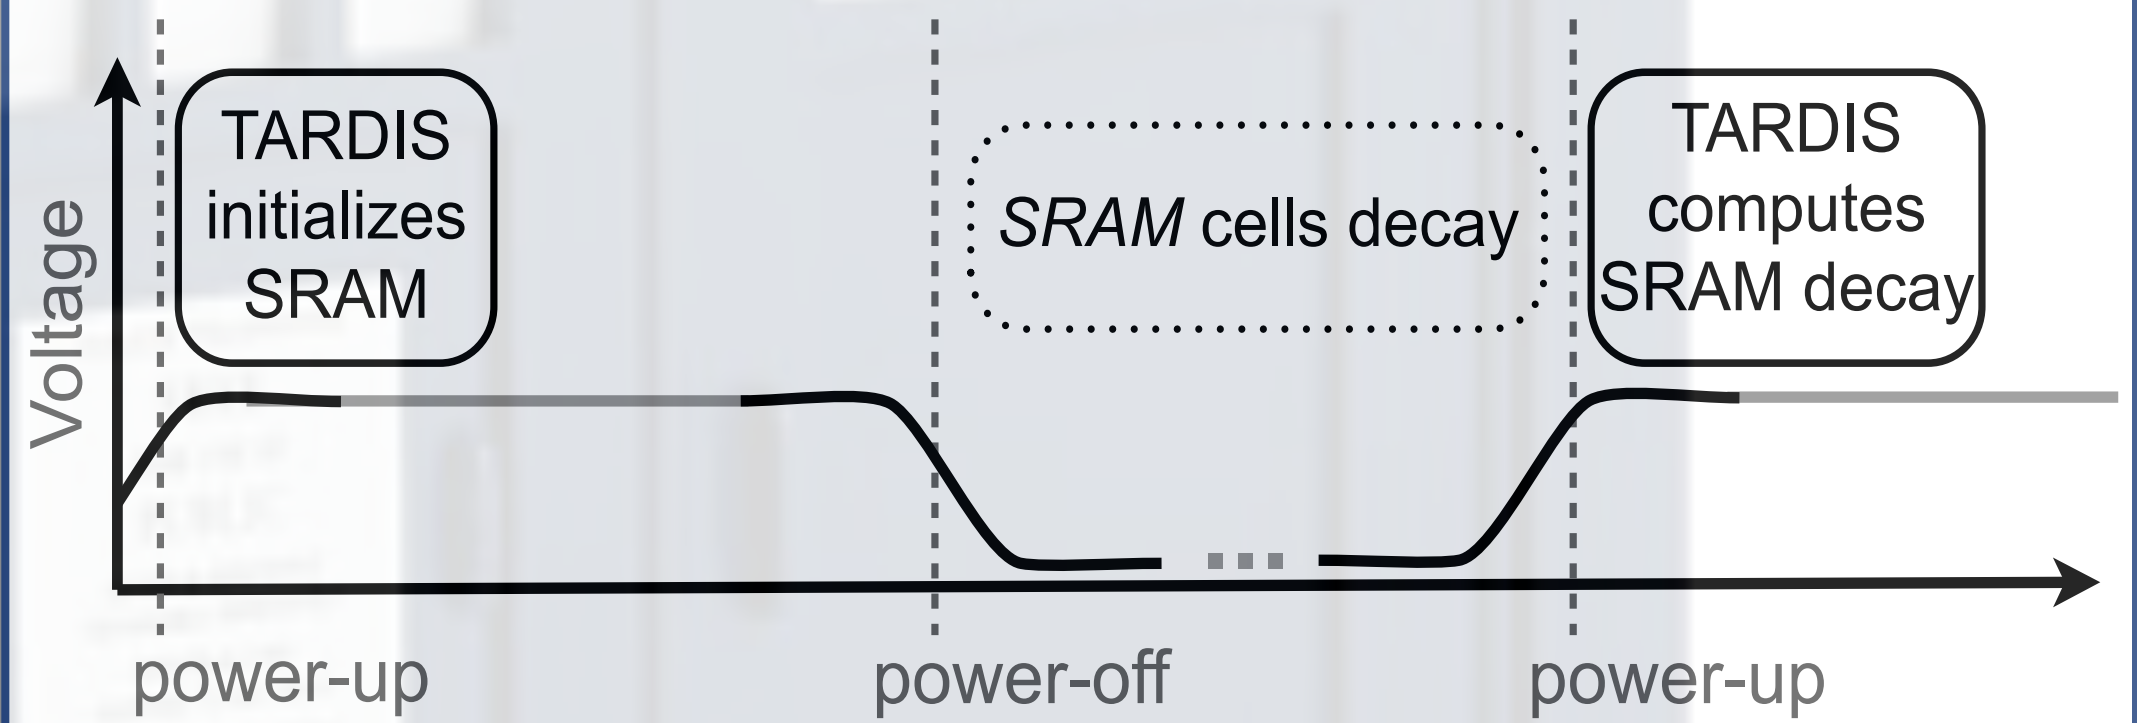

Amir Rahmati (UMass Amherst), Mastrooreh Salajegheh (UMass Amherst), Daniel Holcomb (UC Berkeley), Jacob Sorber (Dartmouth College), Wayne Burleson (UMass Amherst), Kevin Fu (UMass Amherst)

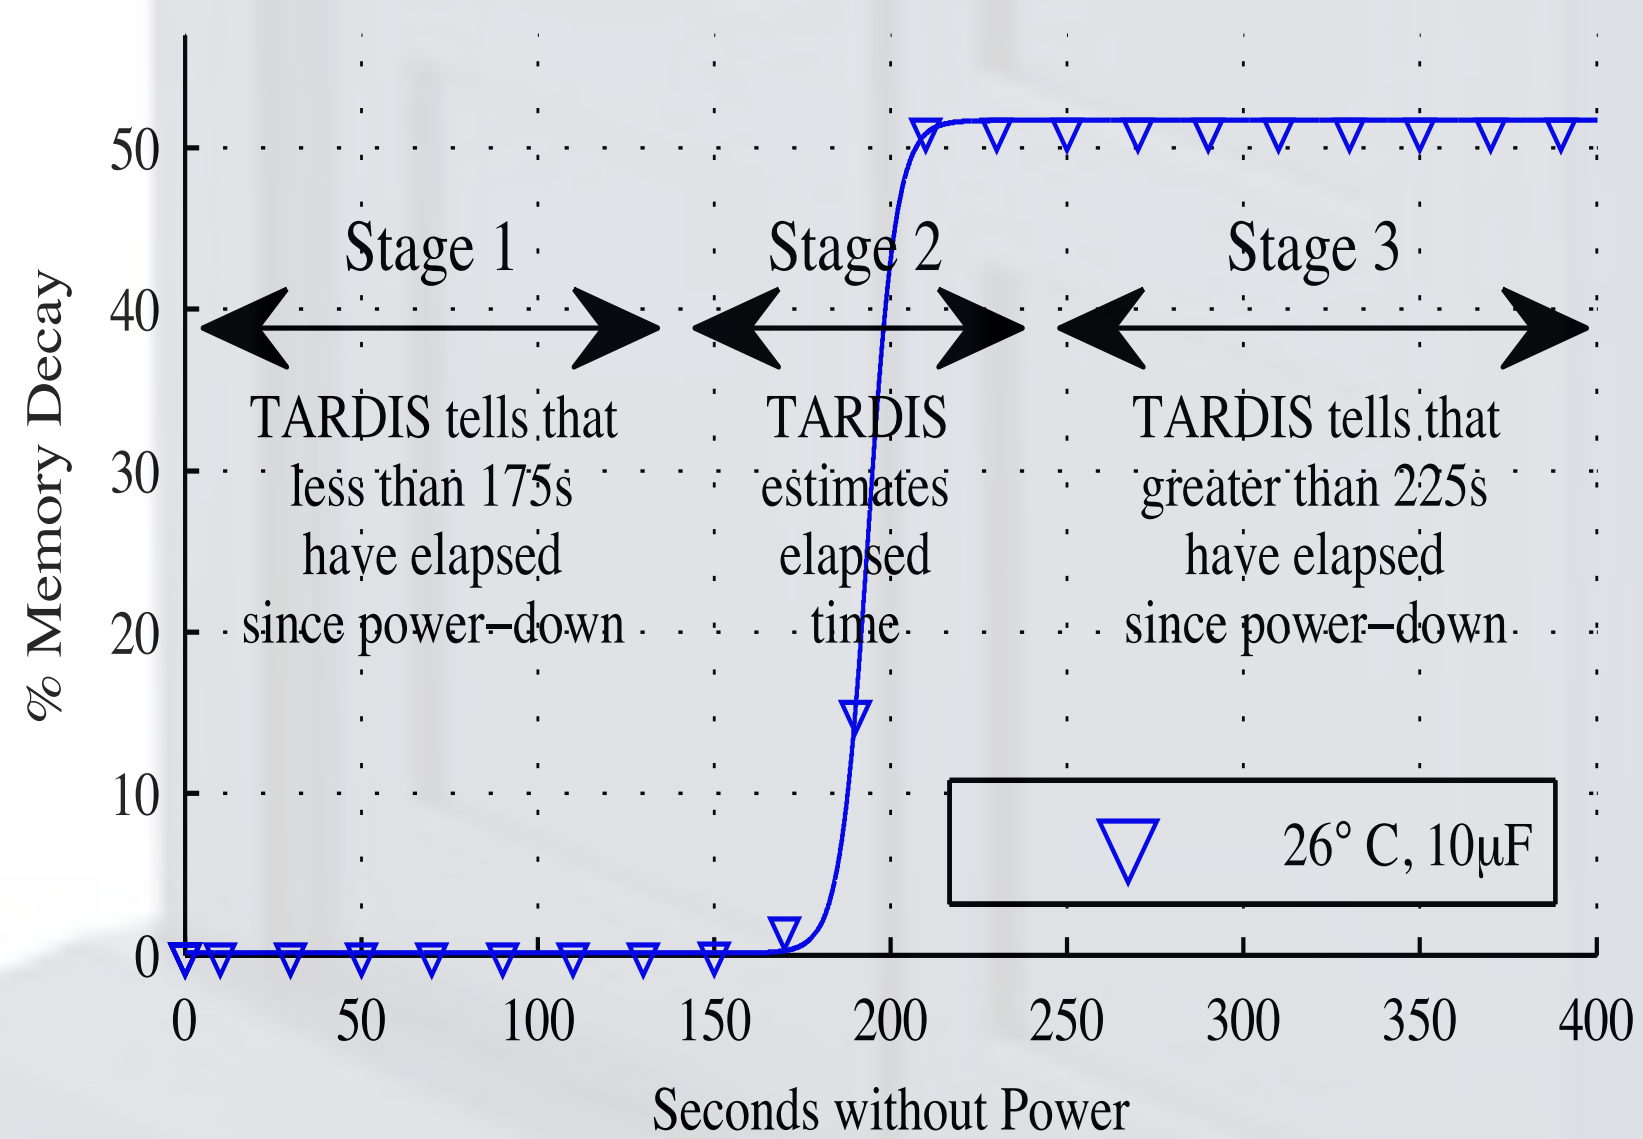

- Smart cards, RFID tags and other intermittently powered devices do not have a notion of time across power ups.
- Lack of a trustworthy clock makes it difficult to implement security protocols.
- Any solution must consider legacy hardware and implementations costs.

SRAM is a **volatile memory** that loses data in the absence of power. This **loss of data is gradual** and depends on the *circuit's specifications, capacitance, and temperature*. TARDIS derives a **notion of time** from the gradual data loss.

TARDIS works by first **initializing a portion of SRAM to 1's**. After a power loss, TARDIS **reads the SRAM** and will use the **decay percentage** (ratio of flipped bits) and the **temperature** sensors present in these devices to maintain a sense of time elapsed.

Estimated power loss duration on a TI MSP430F2131

Time frames can be tweaked based on cap size from few seconds to hours

Applications

- Preventing brute force attacks:

Platform	# Queries
Mifare Classic	>1500
Mifare DESfire	250,000
UHF RFID tags	200
TI DST	~75,000
GSM SIM Card	150,000

- Allowing time-out in security protocols
- Preventing Passback and Double Reads
- Implementing E-coupons
